C1 CONCEPTUAL WATER BUDGET

C1.1 DATA RESOURCES

Using available data, the TRCA study team accounted for the following elements:

- Climate;
- Geology/Physiography;
- Land Cover;
- Groundwater;
- Surface Water (including reservoirs and major discharges); and
- Water Demand.

The integrated conceptual assessments were undertaken where sufficient continuous data exists:

- Stream Gauge Network stream gauge stations (or HYDAT stations), with sufficient periods of record (generally >5 years of continuous data);
- Active or inactive Environment Canada (Water Survey of Canada);
- The climate data collected over 36 years (1960-1996) from the Oshawa airport and the Oshawa Water Pollution Control Plant; and
- Permitted Takings (2005 MOECC PTTW database).

Available climate data obtained from the Environment Canada stations is available from the ORMGP database shared amongst the Coalition of Authorities on the Moraine, the Regional Municipalities of York Peel and Durham, and the City of Toronto. More recent data was queried online from the Environment Canada website by month and added to the historical data where possible. CLOSPA owned climate station data was obtained from an in-house database, though migration of this data to the ORMGP database is underway.

Because most of the local Environment Canada operated stations were decommissioned over the past several years, the spatial distribution of current climate monitoring stations has been identified as a gap locally in the support of current and future local water budgeting, amongst other studies. TRCA is currently investigating, in partnership, the commissioning of a centrally located comprehensive climate station to supplement the existing network. It is anticipated that this station will also collect evaporation data.

Soil classifications are based on the National Soil Database data model for Detailed Soil Surveys found on the CanSIS website (<http://sis.agr.gc.ca/cansis/nsdb/index.html>). Where applicable, Ontario soil data items follow the Canadian System of Soil Classification (2nd Edition) 1987, or The Canadian System of Soil Classification (third edition) 1998.

To complement the thermal classification exercise, airborne thermography is used to collect the locations of springs and seepage areas. Potential springs and seeps in the Oak Ridges Moraine were mapped from Aerial Thermography collected between midnight and 3 a.m. on March 1, 1994. Data is extracted from thermal infrared images that show a contrast in surface temperatures on a cold winter night. In addition, warm areas on the thermal image may coincide with portions of streams and potential reaches of significant groundwater discharge locations, noted as potential open water. Data are then digitized from NTS map sheets into vector format. This information will be combined with available discharge mapping to help increase understanding of groundwater discharge.

Stream gauging provides critical information needed for TRCA's flood forecasting and warning program. This information is also important to water budgeting analyses that are necessary for source water protection. Total flows, baseflows, mean daily flows, and mean monthly flows are derived from the raw level data and stream section survey information.

Methods of Analysis

The purpose of water budget analyses is twofold. They aim to identify watershed communities where the sustainability of water supplies is questionable and to highlight key factors that may limit the sustainability, so that appropriate risk management activities can be completed. This analysis is phased or tiered to focus on areas in need, starting at a regional scale and successively focusing in on smaller areas if necessary. The purpose of the analysis is to:

- Estimate the quantity of water flowing through a watershed;
- Understand the pertinent processes and pathways water follows; and
- Assess the sustainability of water supply sources from a quantity perspective.

The first phase is a regional evaluation of all existing water-related data, focusing on various aspects including climate, land use, surface water, groundwater, and water use in each watershed. This phase is known as Conceptual Understanding and forms the basis for subsequent water quantity work.

The Tier 1 Screening Stress Assessment follows the Conceptual Understanding phase (see **Figure C1-1**) and estimates the amount of water that is used currently and will be needed in the future (demand), and compares this to the amount of water available (supply) minus a reserve quantity (demand/ (supply – reserve)). The reserve quantity represents the amount of water needed to sustain activities outside of drinking water, such as for maintaining groundwater discharge, supporting the ecosystem, diluting sewage treatment plant effluent, and maintaining navigation. Those areas where municipal drinking water supplies (demand) exceed a certain threshold will be subject to further investigations, namely a Tier 2 Refined Stress Assessment. All areas of the province are to conduct the Conceptual Understanding and Tier 1 analyses.

The subsequent Tier 2 analysis, should it be necessary, focuses on a smaller area (subwatershed) and will test the assessment results of Tier 1 using newly collected information and more sophisticated technical tools (e.g., numerical groundwater flow models). Should the Tier 2 results suggest that an area may be experiencing stress from a water quantity perspective, the area will then progress to a Tier 3 Risk Assessment for the local area.

The following sections describe the quantitative conceptual understanding undertaken to date by TRCA. The general steps undertaken to generate the estimates are summarized as follows:

- Description of the watershed conditions, including a summary of streamflow, total precipitation from local gauging stations as well as all other hydrological components;
- Estimation of the groundwater discharge component through hydrograph separations (a range of values dependent on methodology selected);
- Available regional geology models are currently used to determine potential areas of discharge. It is assumed that the amount of groundwater discharge equals groundwater recharge where the change in storage is considered to be negligible within the catchment area. Interflow is included in either of runoff or groundwater discharge;
- Comparison of evapotranspiration calculations to estimates provided in existing subwatershed, drainage or development plan proposals for sensitive areas where possible;

- Water budget output comprised of a watershed-based quantification of hydrological components prepared;
- The mean annual potential evapotranspiration (calculated by the Thornthwaite method);
- Calculate water surplus (infiltration and runoff) according to the methodology of Thornthwaite and Mather (1957). This was calculated using monthly mean temperature and precipitation data for 38 climate stations within or near the Region of Durham; and
- Partition the water surplus into runoff and infiltration according to the coefficient method outlined in Ontario Ministry of the Environment (1995) utilizing soil characteristics, topography, and vegetative cover.

There are also a number of water budget investigations being conducted within TRSPA jurisdiction as part of the Regional ORMGP Groundwater Management Study. The methods being utilized include:

- HSP-F Models (Hydrological Simulation Program – Fortran);
- WABAS (Water Balance Analysis System; Clarifica Inc.); and
- MODFLOW, a three-dimensional numerical groundwater flow model (CAMC-Earthfx, 2006).

HSP-F is a numerical model that is capable of simulating hydrologic processes, pollutant generation and transport processes both within catchments and along watercourse networks. This tool has been used to assess the potential benefits of implementing stormwater management practices. The model was calibrated to streamflow, surface water quality and sewer discharge data.

Water budget estimates for both existing and future Official Plan land use scenarios have been conducted by Clarifica Inc. (2002; 2003a; 2003b) using the WABAS methodology (Graham *et al.*, 1997) for the Upper Humber River watershed, the Petticoat Creek watershed, and the Duffins Creek watershed. Inputs to the model include:

- Daily precipitation;
- Average or maximum daily temperature;
- Pan evaporation;
- Daily streamflow measurements; and
- Physical basin parameters, including imperviousness, interception abstractions, vegetation, and soil characteristics.

The outputs from the model are time series of:

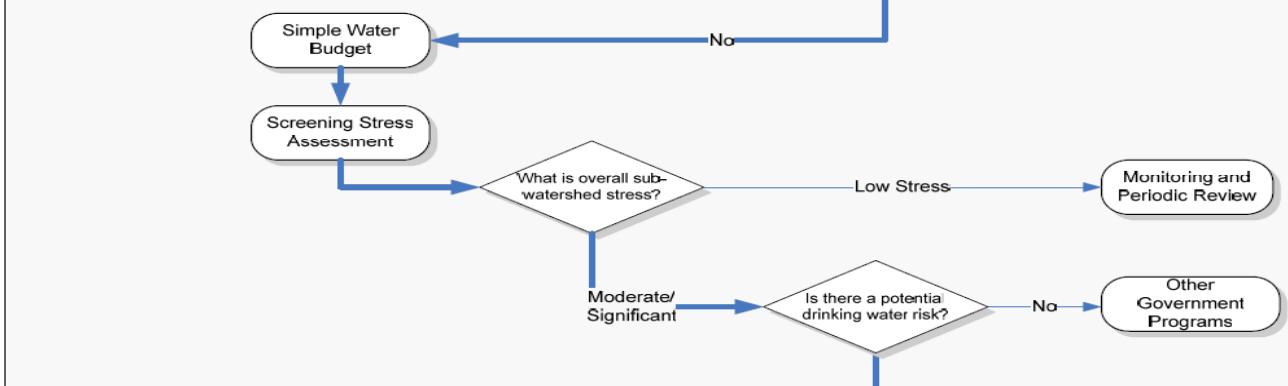

- Runoff;
- Infiltration;
- Evaporation; and
- Storage conditions within each water reservoir (pervious and impervious interception storage, surficial soil storage and snow pack storage).

Flow

Figure C1-1: Water Budget Process

With respect to the regional numerical groundwater flow model (MODFLOW), which encompasses the study area, initial estimates of applied net recharge on a regional scale were developed and used as

input into the Regional Model developed for the ORMGP Groundwater Management Study (Earthfx, 2004).

Data on land use, climate and soil properties were analyzed to provide the initial estimates of the spatial distribution of groundwater recharge. The primary influence on the recharge distribution was assumed to be the surficial geology as mapped by the GSC. The initial estimates used in the model were adjusted during model calibration. Additional calibration is required as the Core Model is applied over the study area. Recharge rates in the preliminary regional model assessment were highest over the Oak Ridges Moraine due to the sandy soils and hummocky topography (360 mm/a) and lowest in areas covered with lake sediments or organic deposits.

Groundwater discharge estimates from streamflow hydrograph separation basically involve removing the runoff or storm/melt events that form peaks on the hydrograph over relatively short durations (hours to days). The groundwater component is considered to be the more consistent contributor to streamflow with annual fluctuations seen as gradual changes in the hydrograph. The three-dimensional numerical groundwater flow model (MODFLOW) being constructed for the Oak Ridges Moraine is using groundwater discharge estimates from hydrograph separation as one of the flux calibration targets.

From daily average streamflow measurements, the groundwater discharge component is assumed to be approximately equal to a 5-day running average of the 7-day running minimum daily average flow. This method is similar to that utilized by the WABAS method (Clarifica, 2002). However, the WABAS method focuses on the runoff component when calibrating the soil moisture balance model. The WABAS methodology was coupled with the MODFLOW model for a pilot water budget analysis for three watersheds within the Lake Simcoe Region Conservation Authority (Earthfx Inc. and Gerber Geosciences Inc.)

The reader is referred to the Conceptual Water Budget report for the TRSPA jurisdiction prepared by Gartner Lee (2007).

C1.2 LIMITATIONS: DATA AND METHODS

Efforts were made throughout the conceptual water budget assessment to identify database management gaps, key analytical gaps and knowledge gaps. These gaps are being addressed where possible in facilitating the move forward activities.

C1.2.1 DATABASE MANAGEMENT

Data management refinement arises when database structures are no longer functional for the required analysis or are not scalable or linkable. In addition, gaps arise when database population or metadata tracking are required. Gaps are addressed recognizing the appropriate scale of the specific study being undertaken. Gaps have been identified for water budgeting purposes and are primarily related to (**Table C1-1**):

- Streamflow stage-flow relationships;
- Hydrologic and water use database structure development; and
- Data loader and ArcHydro development.

Table C1-1: Data Management Needs

| Data Management | | | |
|---|---------------------------------------|-----------------|---|
| WC Deliverable | Data Set Name or Source | Data Problem | Comment |
| Integrated Hydrologic Database | Hydrologic data | Requires update | ORMGP database data loader requires structure update. |
| Oak Ridges Moraine Groundwater Program (ORMGP) Hydrogeologic Database | Various data sources | Requires update | Additional monitoring locations/data to be imported. |
| PTTW Database | MOECC PTTW data and field survey data | Requires update | Internal database to be developed/populated. |

C1.2.2 DATA LIMITATIONS

Data that are undergoing refinement have been identified for water budgeting purposes and are summarized in **Table C1-2**. Identified items are generally consistent with those reported in the characterization report:

- Future development areas;
- Surface water thermal classifications;
- Seepage and springs delineation;
- Serviced/unserviced areas and stormwater management facilities;
- Precipitation distribution, and evaporation; and
- Spatial and temporal distribution of low flows.

While some of these gaps have been dealt with in this revision, (e.g., thermal classification), several more will be addressed during the Tier 1 reporting.

Table C1-2: Data Limitations

| Identified Data that is undergoing Refinement (not available at the time of reporting) | | | |
|---|---|--------------------------------|---|
| Water Budget and Stress Assessment | | | |
| Component | Data Set Name or Source | Data Problem | Comment |
| Integrated Hydrologic Database | Hydrologic data | Requires update | ORMGP database data loader requires structure update. |
| Oak Ridges Moraine Groundwater Program (ORMGP) Hydrogeologic Database | Various data sources | Requires update | Additional monitoring locations/data to be imported. |
| Gauge Database/Installations | TRCA data | Requires update | Internal database to be developed/populated. |
| Stormwater Management Facilities Map | Upper/lower tier municipalities; Field verification | Partially populated | Data requested. |
| Precipitation Distr. Map ET Zone Map (draft PRMS map included) | AES (CDCC), TRCA data | Partially populated too sparse | Data gaps to be filled. Maps to be completed. |
| Seepage and Springs Map | TRCA field program | Partially populated | Field surveying and digitizing required. Historical Thermography mapping is included. |
| Aggregate Resources Update | MNRF OGDE, MNDM, municipal, field surveys | Partially populated | Existing data requires orthophotography review to verify locations. |
| Integrated Monitoring Network Site Locations and Data Review | TRCA, Region studies | Requires update | A review of monitoring needs is required. Paucity of climate data to be addressed. |
| Water Well Information System (WWIS) | MOECC data and field survey data | Requires update | Data requested. |
| Knowledge Gaps | | | |
| Refinement of aquifer characterization and flow system understanding including the orientation of bedrock valley systems and significant area recharge and discharge mapping; Ongoing refinement of the existing surface water understanding (refining the tested PRMS model); Ongoing refinement of the existing groundwater flow understanding (refining the existing Core MODFLOW model); Understanding of the interaction of the surface water and groundwater flow, including wetlands, within the system; Development of acceptable water use targets to protect both the resource and the aquatic ecosystem; Development of methodology and tools to provide potential spills response analysis which will involve overland flow, stream travel and groundwater flow including the unsaturated zone transport; and A more comprehensive understanding of the Q _{DEMAND} components of the water budget, including assessing the permits and actual water use. | | | |

Knowledge gaps identified relate to the analysis and tool adjustment required to quantify the water budget estimates and to understand how the flow system operates. These tools enable predictions of impacts from potential future changes such as climate or land use change. Identified knowledge gaps with respect to the conceptual (to date) include:

- Refinement of aquifer characterization and flow system understanding including the orientation of bedrock valley systems and significant area recharge and discharge mapping;
- Refinement of the existing surface water understanding (refining the tested PRMS model);
- Refinement of the existing groundwater flow understanding (refining the existing Core MODFLOW model);
- Understanding of the interaction of the surface water and groundwater flow, including wetlands, within the system;
- Development of acceptable water use targets to protect both the resource and the aquatic ecosystem; and
- Development of methodology and tools to provide potential spills response analysis which will involve overland flow, stream travel and groundwater flow including the unsaturated zone transport.

C2 TIER 1 WATER BUDGET AND STRESS ASSESSMENT

C2.1 METHODS OF ANALYSIS

The Tier 1 Water Budget methodology assessed the existing hydrologic conditions within the watershed using both Conceptual Understanding and numerical modelling information developed through the Source Water Protection program and the ORMGP Groundwater Study reporting. The conceptual model development involved the collection and analysis of baseline information related to climate, surface water and groundwater.

The purpose of a Tier 1 analysis is to estimate the hydrologic stress of subwatersheds in order to screen out areas that are unstressed from a water quantity perspective. Future efforts and resources (Tier 2 and Tier 3) can then focus on areas that are stressed. At Tier 1, for each subwatershed, the *Technical Rules, Nov 2009*, require the evaluation of two scenarios: (1) current conditions; and (2) 25-year future demand. The goal of the current conditions scenario is to identify subwatersheds that are under stress as a result of existing water takings. The goal of the 25-year future scenario is to identify additional watersheds that may become stressed as a result of additional drinking water requirements.

A planned subset of objectives specific to TRCPA's Tier 1 numerical modelling is noted below:

- Quantify components of the hydrologic cycle;
- Apply tools for use in analysis;
- Improve understanding of the groundwater system;
- Define links between shallow and deeper flow;
- Assess changes due to groundwater/surface water withdrawal, urbanization, and climate change;
- Provide spatial mapping of hydrological components;
- Support an understanding of flow regimes in un-gauged watersheds or watershed with a paucity of data;
- Determine levels of stress (i.e., demand vs. available water); and
- Ultimately help identify risks to the watersheds in a process consistent with provincial guidance.

Following the Conceptual Understanding phase is the Tier 1 Screening Stress Assessment. Tier 1 estimates the amount of water that is used currently and will be needed in the future (demand), and compares this to the amount of water available (supply) minus a reserve quantity (demand/(supply – reserve)). The reserve quantity represents the amount of water that is deemed necessary to sustain other activities outside of drinking water use such as for maintaining groundwater discharge, to support the ecosystem, to dilute sewage treatment plant effluent, to maintain navigation, etc. Those areas where municipal drinking water supplies (demand) exceed a certain threshold will be subject to further investigations, namely a Tier 2 Refined Stress Assessment.

The schematic shown in **Figure C2-1** depicts the processes used by the numerical models. A modified Precipitation-Runoff Modelling System (PRMS: surface water model) code developed by the United States Geologic Survey (USGS) was used to estimate quantitatively the various water budget fluxes such as precipitation, interception, evaporation, potential and actual evapotranspiration, snowmelt, runoff, and groundwater interflow and infiltration (Earthfx, 2007).

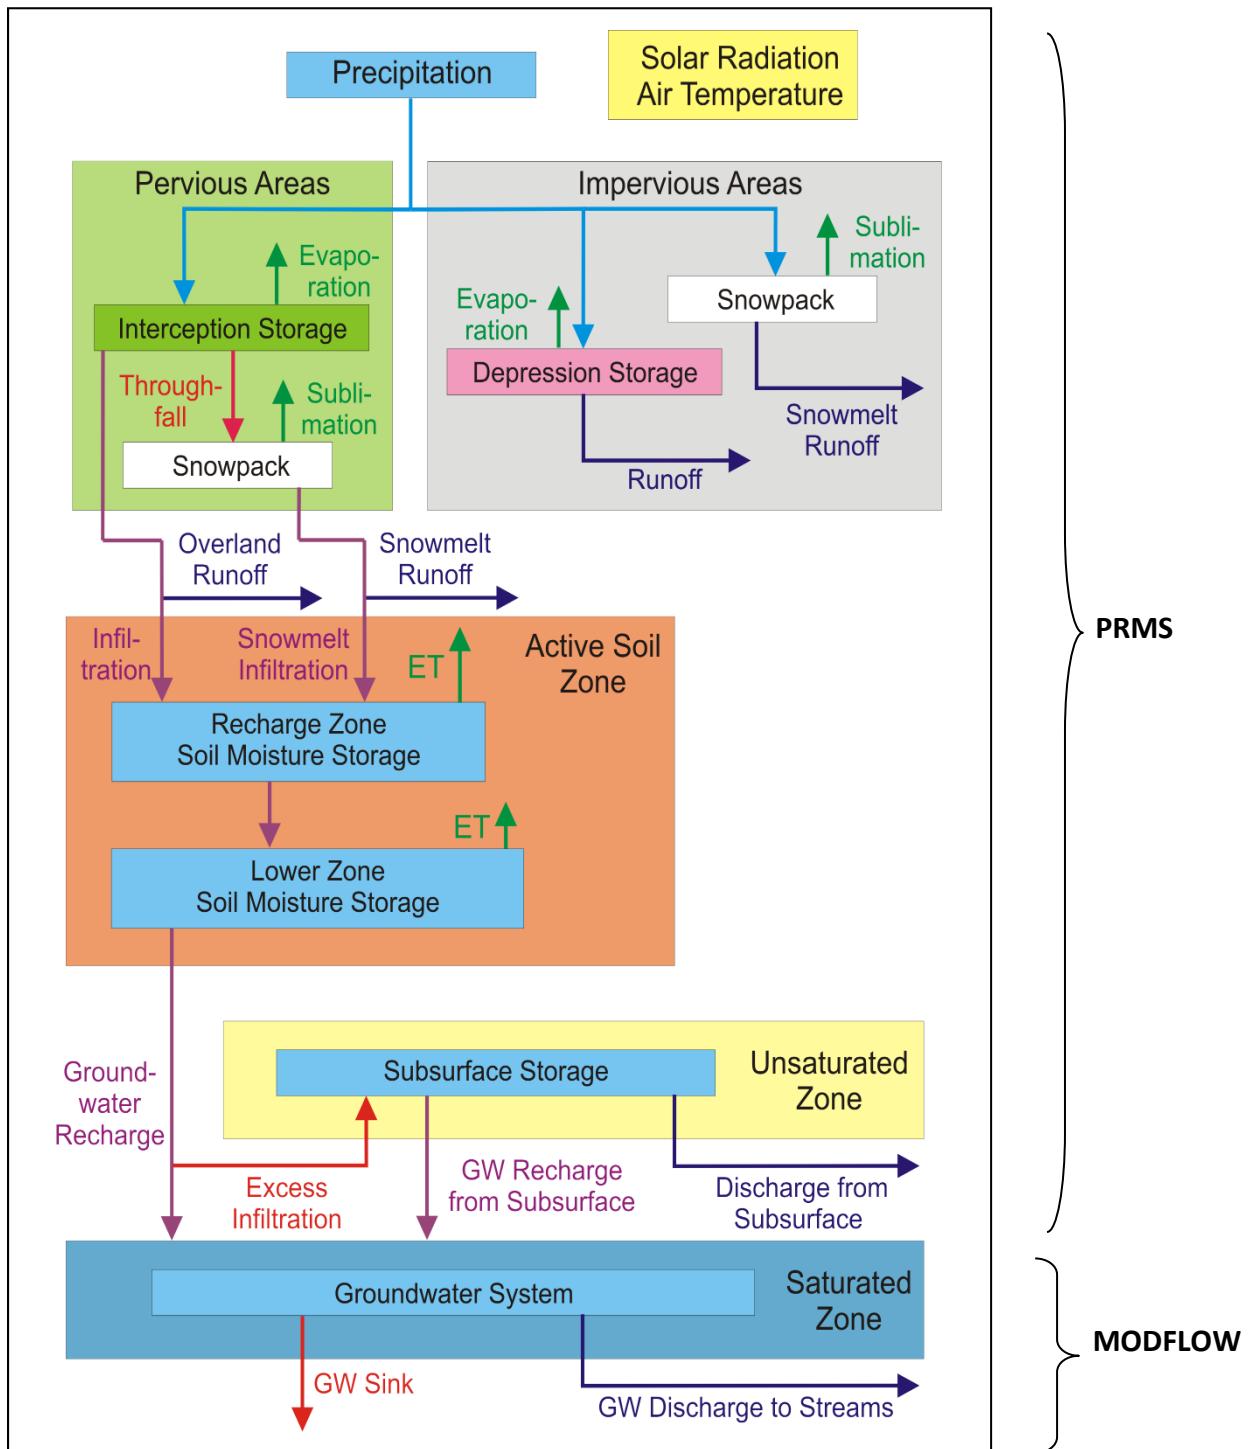

Figure C2-1: PRMS/MODFLOW model process integration (Earthfx, 2007)

The model integrates watershed characteristics, such as slope, aspect, elevation, soils, land use and cover, precipitation, snowpack, temperature, and solar radiation. Square cells, 25 metres on a side, were used to represent the distribution of the characteristics within the watershed, and a daily water balance was calculated for each cell for the simulation period. Daily averages were then averaged over a 19-year simulation period to determine the long-term average annual millimetres per year (mm/yr) for each water budget component. The model was calibrated to total surface water flow data and baseflow estimates from stream gauging, and to the groundwater flow model simulations.

The groundwater model, referred to as the “West Model,” was used to simulate groundwater budget components such as groundwater levels and groundwater discharge to streams (Earthfx, 2007). The model integrates data on the physical, geologic, and hydrologic features that govern groundwater flow in the watershed. Calibration was conducted in a trial-and-error process where results of successive model runs were primarily matched to hydraulic heads and flows interpolated from observed static water levels obtained from the MOECC Water Well Information System (WWIS). Matching baseflow in the watershed was a second calibration target. A post-processing program was used to determine lateral groundwater inflows and outflows (underflows) across the watershed boundaries. These underflows were used to adjust the calibration of both the PRMS model and the simulated groundwater discharge from the MODFLOW model.

A surface water model such as PRMS, due to its simplified representation of the groundwater flow processes, may not calibrate properly to observed streamflow if the watershed is gaining or losing significant quantities of groundwater underflow across the watershed boundary. For instance, if the stream gauge data when normalized to the drainage area above the gauge indicates higher rates of normalized flow than recorded at other gauges outside of the watershed, it may indicate that the additional flow is attributable to groundwater inflow from outside the watershed. If this groundwater inflow is not accounted for, the surface water model would need to be adjusted to account for additional groundwater recharge in the watershed. Iteratively calibrating the surface water model (PRMS) to the groundwater flow model (MODFLOW) provides a check on the simulated rates of recharge.

For example, if the PRMS model computes recharge rates that are higher in an area than the groundwater system can transmit, the MODFLOW model will simulate groundwater levels to be much higher than observed. Conversely, if recharge rates are too low, the simulated groundwater levels will also be low. This cross-calibration exercise between the two models also provides a method of determining the net underflow across watershed boundaries. These flows can be subtracted from the observed flows measured at the stream gauge to re-estimate recharge within the watershed. This type of coupling of models is termed “loosely coupled” as they are not directly connected to each other.

The reader is referred to the Tier 1 Water Budget report for the TRSPA jurisdiction prepared by TRCA (2010).

The terminology of the water budget parameters used in this chapter consist of Precipitation (P), Net Precipitation (Pnet or precipitation minus interception), Interception (I), Actual Evapotranspiration (AET), Groundwater Infiltration (GWI), Groundwater Lateral (underflow) in (GWLin) and out (GWOut) of the watershed, Discharge to Streams or Groundwater Discharge (GWD) and Runoff (RO). For the purposes of this chapter, GWI is assumed to include groundwater interflow to streams and groundwater recharge to the saturated zone.

Water withdrawals are represented by groundwater use or surface water use. These water budget components represent the key items discussed in this chapter. Long term average annual values of Pnet,

I, AET, GWI, GWD and RO are reported at a watershed and subwatershed scale, along with mapping of areas of GWI and GWD.

Water budget estimates are typically normalized to units of millimetres of water distributed over a drainage area per year (mm/yr or mm/a). This is accomplished by converting flow or accumulation rates (e.g., m³/s or L/s) to total volumes per year, and then dividing by the contributing drainage area.

The most important source of water use information was the TRCA Water Use Assessment database, built upon the MOECC PTTW database. The TRCA validated the MOECC PTTW database between 2003 and 2005 in the field and has been updating this database over the past two years through Environmental Bill of Rights registry postings and MOECC application notifications. Field surveys of local water users collected estimates of actual usage rates, which are generally much less than the maximum permitted rates. Additional water use assessment studies completed by the regions of Peel, York and Durham were amalgamated into the final dataset (Marshall, Macklin, Monaghan, 2006; Golder Associates, 2003; Gartner Lee, 2003; Beatty and Associates, 2003). The regions of Peel, York, and Durham subsequently provided an update of monthly groundwater use for all of their active municipal wells.

Non-serviced domestic water use was calculated by combining the unserviced population estimates by subwatershed with estimated per capita demand of 335 L/d/person from the Environment Canada water use website (www.ec.gc.ca). This value is consistent with the value recommended in *Guidance Module 7*.

While efforts have been made to accurately present the findings reported in this chapter, factors such as significant digits and rounding, digitizing and data interpretation may influence results. For instance, in data tables no relationship between significant digits and level of accuracy is implied, and values may not always sum to the expected total.

C2.2 LIMITATIONS: DATA AND METHODS

Empirical methods used to analyze simple functions of physical systems have identified limitations, such as relying on limited available data, or in the application of scale. These methods either simulate at a point or simulate a large area as a single value limiting the ability to scale down to a local area or to distribute water reservoir estimates spatially (Ely, 2006). Process-based numerical models that compute distributed water budgets are used to simulate hydrologic processes at varying scales using generally readily available data (Ely, 2006). Numerical models are generally deterministic meaning they are based on physical theories and equations and are generally referred to as physically based models. Lumped models simplify physical characteristics by treating catchments as singular response areas using spatially averaged parameters over each area. Distributed models discretize the spatial variation of physical features into a grid or cell-type representation (Barth, 2005). The lumped approach is generally used in conceptual models, whereas distributed physically based models are used for more detailed spatial and temporal analysis and scenario testing.

C2.3 UNCERTAINTY, DATA AND KNOWLEDGE

Uncertainty is inherent in the water budget estimation process. The accuracy of estimates relies on the:

- Quantity and quality of the input data (e.g., related to streamflow, climate, groundwater well records);
- Conceptual understanding of the watersheds; and
- Modelling calculation methodology.

Overall, the issues related to uncertainty, data and knowledge gaps are complex and highly qualitative. There is a degree of uncertainty associated with every aspect of the water budget analyses. However, it is impossible to provide a quantitative assessment of the level of uncertainty. Rather, one can only say, in very general terms, that the level is low, moderate, or high.

The *Technical Rules, 2009* suggests that it would be reasonable to expect a low level of uncertainty in areas where data density is high, where hydrogeologic studies have been conducted, and where numerical models have been developed. This study generally satisfies all three of these criteria. It is recognized, however, that all hydrogeologic analyses have an intrinsic level of uncertainty, because one can never have enough data to fully know how conditions vary in the subsurface.

Development of the ORMGP Core Model entailed a comprehensive process of (1) collecting and filtering the large amount of water well, monitoring well, and other geologic data; (2) interpreting the geologic logs as best as possible and building a conceptual geologic model; (3) assigning initial estimates of aquifer properties and recharge rates and then refining the estimates through model calibration; and (4) performing statistical and sensitivity analyses to demonstrate the validity of the model calibration. The report by Kassenaar and Wexler (2006) documents the procedures and focuses a great deal of attention on answering the questions related to assessing model uncertainty.

While these independent review comments increase the comfort level with the results of the modelling process, there is still the recognition that geologic data are always incomplete and that the WWIS data used in a large part to develop the models has a high degree of error and uncertainty. Data obtained from municipal monitoring networks and other high-quality sources have less uncertainty and have provided useful information in the vicinity of the municipal wellfields. The number of wells and spatial coverage of high-quality data are limited compared to the WWIS data, however. It is recommended that CLOSPA continue to improve its monitoring network over time and incorporate the available high quality data, especially within the higher stressed watersheds, and thereby reduce the level of uncertainty associated with the numerical models.

Computer models are a simplification of the real world, built from limited and potentially erroneous data, so their results should be considered with care and independently verified. It should be recognized that the passage of time affects the information provided. Environmental conditions can change. Computer simulations are based upon information that existed at the time the data and model was formulated.

C2.4 SURFACE WATER STRESS ASSESSMENT

The surface water supply values for each subwatershed by month are provided in **Table C2-1**. The monthly reserve values are in **Table C2-2** and the estimated monthly demand values are in **Table C2-3**. Surface water stress assessment results summary is in **Table C2-4**.

Table C2-1: Surface Water Supply Values (QP50) in m³/s

| Watershed | Catchment | Jan | Feb | Mar | Apr | May | Jun | Jul | Aug | Sep | Oct | Nov | Dec |

C2.5 SURFACE WATER SUPPLY AND DEMAND

As discussed in **Section C3**, surface water stress assessment calculations utilized flow percentiles, based on daily data for the 8-year modelling period. Total supply was estimated as the median monthly flow (Q_{P50}), and reserve estimates were based on the 90th percentile flow (Q_{P90}). **Figure C2-2 to Figure C2-15** show the simulated results as compared to observed values for gauged catchments in the TRSPA watersheds. These flow duration curves show that typically the model provided conservative estimates of stream flow when compared to observed data.

Given the relatively high percentage values found in the surface water stress assessment (**Section C3**), monthly supply (total supply – reserve) and monthly demand were plotted for catchments that were assigned a significant classification. This allowed for better visualization of the timing and extent of demand. These graphs (**Figure C2-16 to Figure C2-21**) show that stresses in the TRSPA are typically due to low supplies in August, when demand is at its peak and there is ample water to meet demands on an annual basis, reinforcing the need for large scale water users to utilize storage reservoirs for irrigation purposes.

C2.6 ASSESSMENT OF REQUIRED STORAGE

Additional analysis was performed on the >100% catchments, to determine the cause of these results, where irrigation storage ponds / reservoirs were examined. This analysis was to investigate if these storage features had sufficient storage to account for the demand of water that is over and above the estimated in-stream supply. While it was not possible, in the scope of a Tier 1 Assessment, to complete this analysis for all surface water users, it was felt that a representative sample should be explored in more detail to validate catchments where demand is greater than available supply.

In this evaluation, the total demand was subtracted from the available supply for each month. Where the supply is less than the demand, a negative number is the result. These are then summed and converted to a total volume (m^3), which represents the total water required to meet a specific user's demand over and above available in-stream supply. This volume is then calculated to a 'required depth of storage', based on the surface area of the storage feature. If the required depth of storage was calculated to be more than 2.5 m (based on typical golf course pond depths) there may be an error in the demand or supply estimates.

This analysis was performed for catchments CA01 and HU04 as both of these catchments were calculated as having demand >100% of supply and both catchments had only one (primary) surface water user. **Table C2-5** and **Table C2-6** show the results of these calculations. In both instances, the required depth of storage was low, at 16cm and 14cm, respectively. These results confirm that any demand greater than available supply can be accounted for by the storage feature(s).

Table C2-5: Required Depth of Storage Calculations – Catchment CA01

C2.7 GROUNDWATER STRESS ASSESSMENT

C2.7.1 CALCULATIONS

The groundwater stress assessment calculations are summarized in **Table C2-7** to **Table C2-12** and the groundwater usage data are provided in **Table C2-13**. The current and future water use by subwatershed is provided in **Table C2-14**, **Table C2-14** and **Table C2-15**, respectively. The complete stress assessment results by month for current conditions are provided in **Table C2-16** to **Table C2-27**. The stress assessment results under future conditions are provided by month in **Table C2-28** to **Table C2-39**.

Further details are provided in the Tier 1 Water Budget report issued for the TRSPA in 2010 (TRCA, 2010).

C2.7.2 INPUTS TO STRESS ASSESSMENT CALCULATIONS

The inputs from the MODFLOW groundwater model to the groundwater stress assessment calculations include estimates of:

- Groundwater recharge (Q_R in stress assessment tables);
- Groundwater discharge ($Q_{Reserve}$ in stress assessment tables); and
- Groundwater inflows to each subwatershed (Q_{IN} in stress assessment tables).

Groundwater Inflows

Groundwater inflows for each subwatershed are represented as the Q_{IN} values in the stress assessment tables.

C2.8 STRESS ASSESSMENT SUMMARY

This study meets all of the Tier 1 requirements for all of the TRSPA. It includes an enhanced understanding of water use because of TRCA's water use field survey, and enhanced stress calculations because of the complex surface and groundwater models used in the analysis. MNRF has agreed that this assessment meets the main requirements of a Tier 2 Assessment for Whitchurch-Stouffville area. Although a 2-year drought simulation for the Whitchurch-Stouffville area was not completed, the results of this scenario would only increase the calculated stress levels provided in this study. The final maps are presented in **Chapter 3** of the body of this Assessment Report.

Based on this Tier 2 analysis, the Whitchurch-Stouffville area, which includes portions of two subwatersheds (Little Rouge Creek and Stouffville/Ressor Creeks) is recommended for further assessment at the Tier 3 level. This area contains the wellheads for the Whitchurch-Stouffville municipal groundwater supply wells. Although the 2-year drought simulation was not completed for these subwatersheds, the calculated stress levels for these watersheds are above thresholds for the current conditions. Therefore, with the agreement of the MNRF, a Tier 3 or local area stress assessment should be completed in this area. The Tier 3 analysis will be led by the Region of York in partnership with TRCA and the Region of Durham. The project will examine cross-watershed groundwater flow and local recharge in more detail, as well as water use and ten-year drought scenarios.

C3 TIER 3 WATER BUDGET AND LOCAL AREA RISK ASSESSMENT

Well System Characterization Graphs

The following discussion and graphs were obtained from the York Tier 3 Water Budget report (Earthfx, 2013) and present the well system characterization information for the municipal wells that fall within the TRSPA Tier 3 stressed watersheds. Specifically, the graphs present:

- The field measurements used to determine the Safe Additional Drawdown.
- Results from the transient numerical simulations showing the maximum drawdown in the well observed during the 10-year drought simulation.
- Well Construction and Pump Information: To the left of the graph is a schematic presentation of the well construction, well screen and pump level within the well.
- In-Aquifer Geometry (Aquifer top and bottom): To the right of the graph are dotted lines indicating the top and bottom of the aquifer.
- In-well Water Levels: Where available, water levels recorded in the well, such as from air-line measurements, are presented to illustrate operational levels and well efficiency.
- Aquifer Water Levels: Water levels recorded in nearby monitoring wells are displayed.
- Individual Well and Total Wellfield Production: The pumping rate for the individual well, as well as the overall wellfield takings, are displayed to aid in the assessment of the water level data. The scale is on the right side of the graph.

Note that while a longer period of record is presented, the focus of the Risk Assessment is on the “Study Period” of 2010 – 2011.

Safe Additional Drawdown

An important aspect of the graph is the presentation of the information used to determine the “Safe Additional Drawdown”. The safe additional drawdown, is selected based on the lesser of:

- (A) The additional available drawdown in the well, as determined by the difference between the operating level in the well and the top of the well screen. (This is based on the assumption that water levels should not be drawn down into the well screen during operations.)

Or:

- (B) The additional available drawdown in the aquifer nearby the well, as determined by the difference between the aquifer water levels (during the study period) and the top of the aquifer. (This is based on the assumption that the aquifer should not be dewatered in the vicinity of the well.)

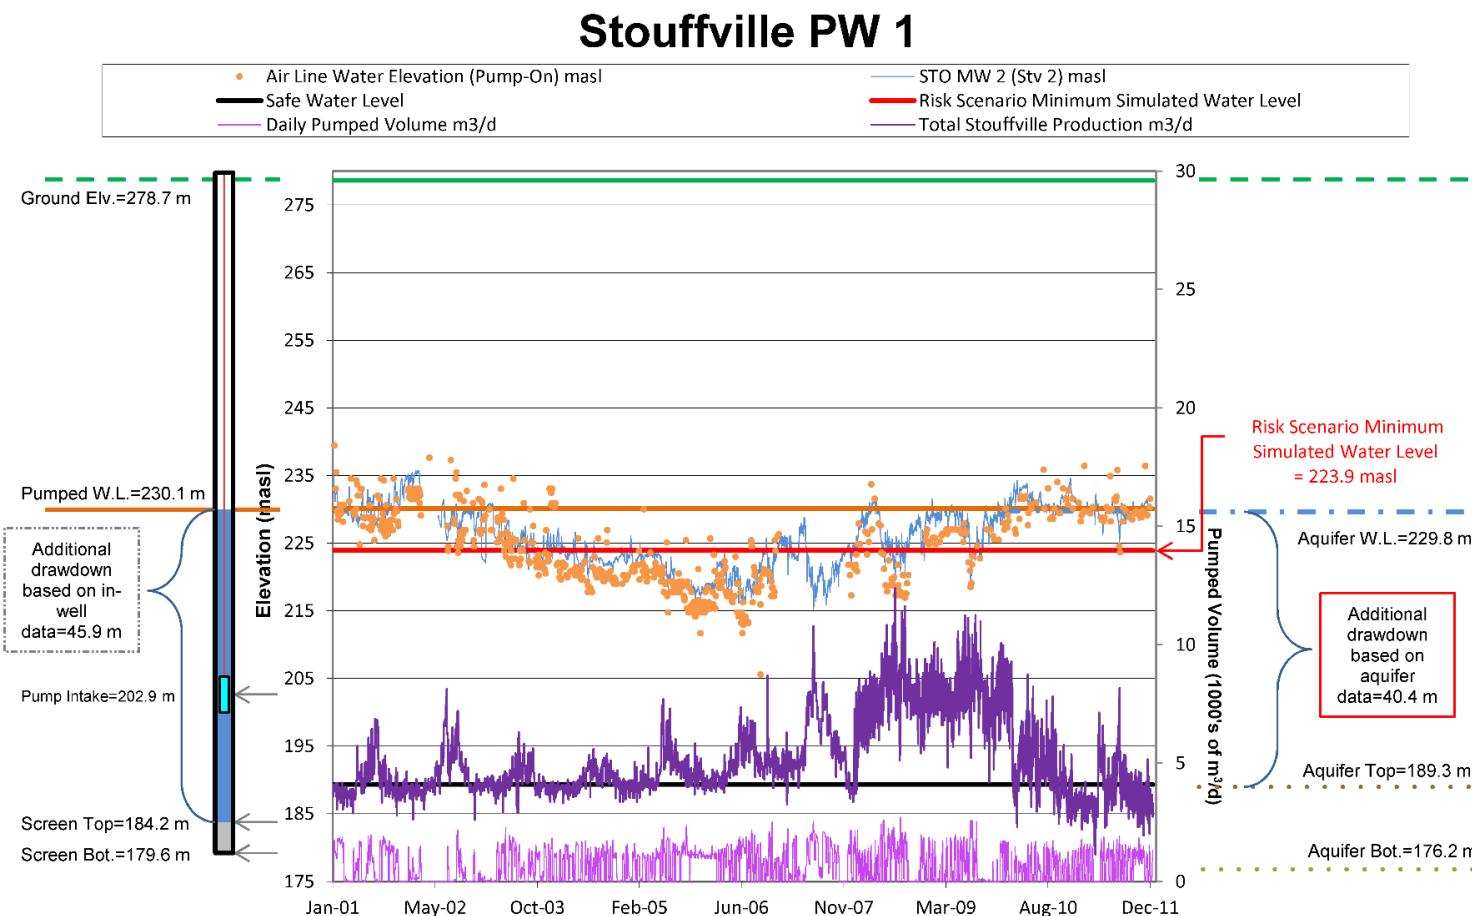

The Safe Additional Drawdown is highlighted on each graph with a red box.

Stress Assessment Maximum Drawdown Level

Safe Water Level (thick black line): This is the lowest water level that is considered acceptable for long term operation of the well.

Risk Scenario Minimum Simulated Water Level (thick red line): This is the lowest predicted water level estimated from the model simulations. Where this level is below the Safe Water Level the well is subject to further risk assessment analysis.

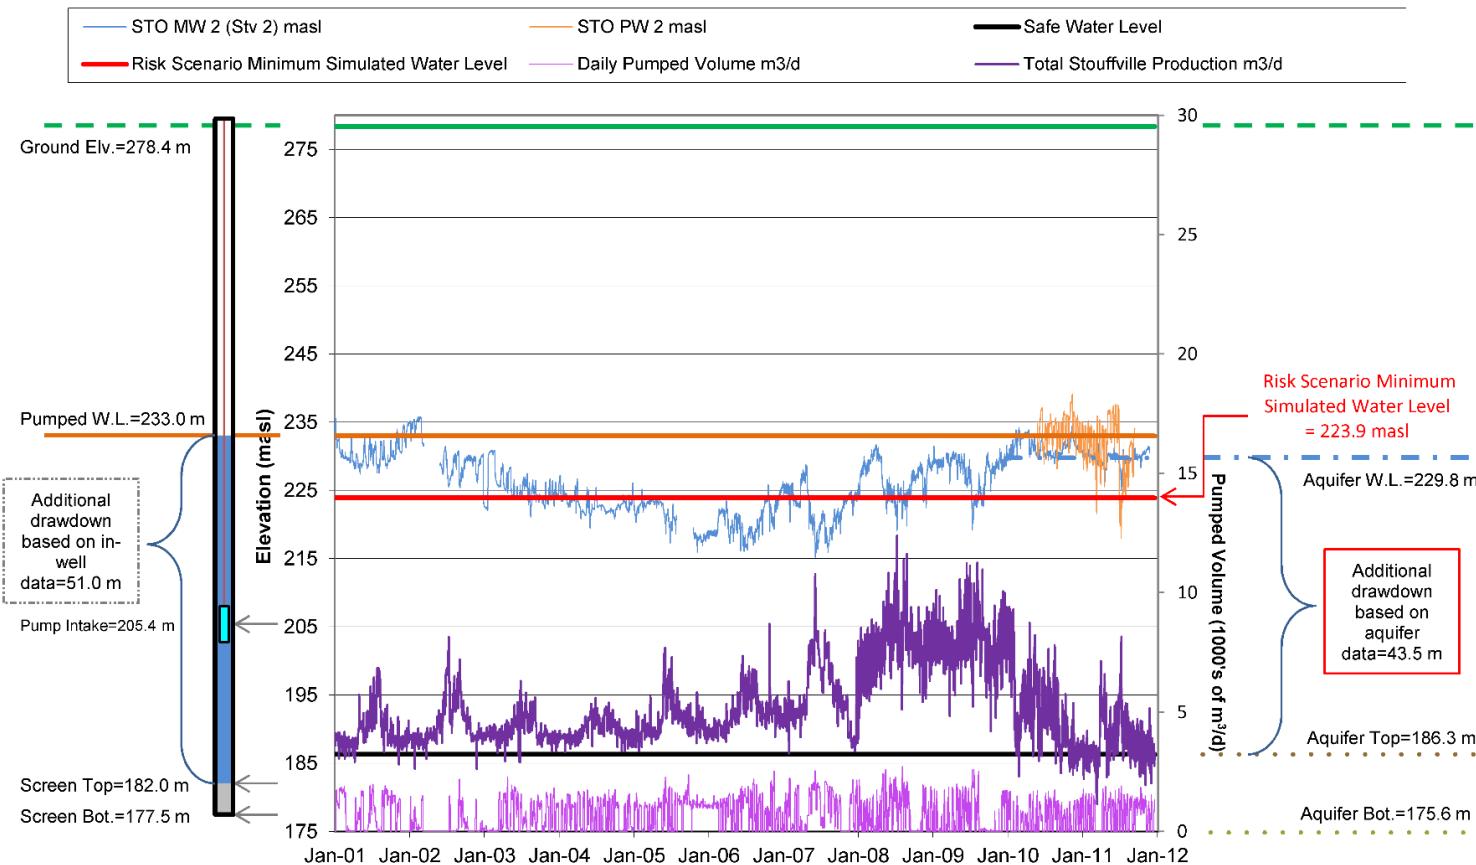

York Region Tier 3 Water Budget - Available Drawdown Hydrographs

Note: Safe additional drawdown for this well selected based on aquifer data as shown in the red box. Pump intake level can be adjusted and is therefore not a constraint. Aquifer water level for 2010-2011 estimated from Stouffville MW#2 at a distance of 4.6 m. The operational/pumped water elevation has been estimated using the on-site monitoring well.

York Region Tier 3 Water Budget - Available Drawdown Hydrographs

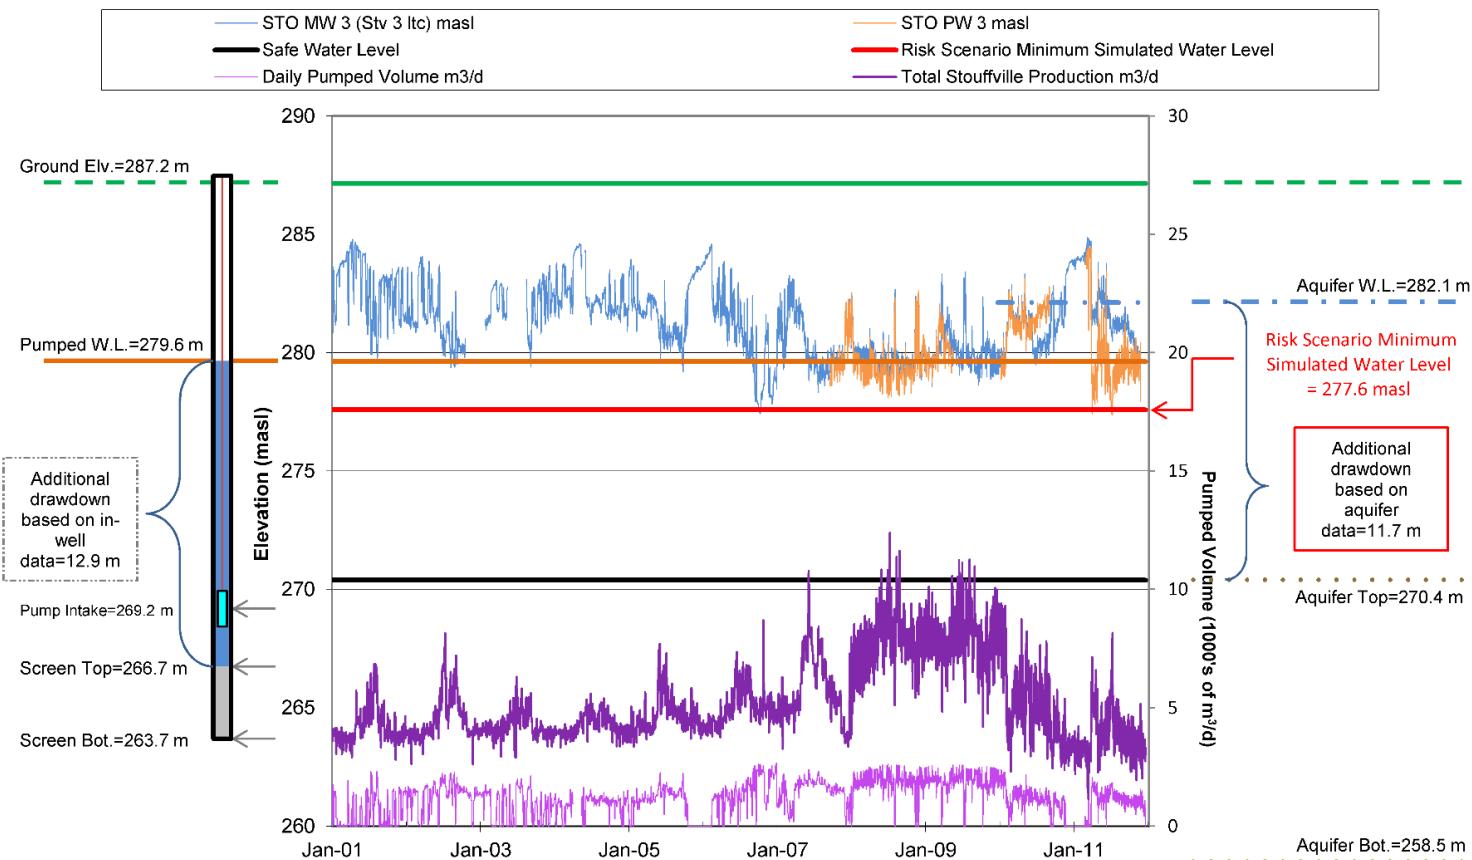

Stouffville PW 2

Note: Safe additional drawdown for this well selected based on aquifer data as shown in the red box. Pump intake level can be adjusted and is therefore not a constraint. Aquifer water level for 2010-2011 estimated from Stouffville MW#2 at a distance of 22.6 m.

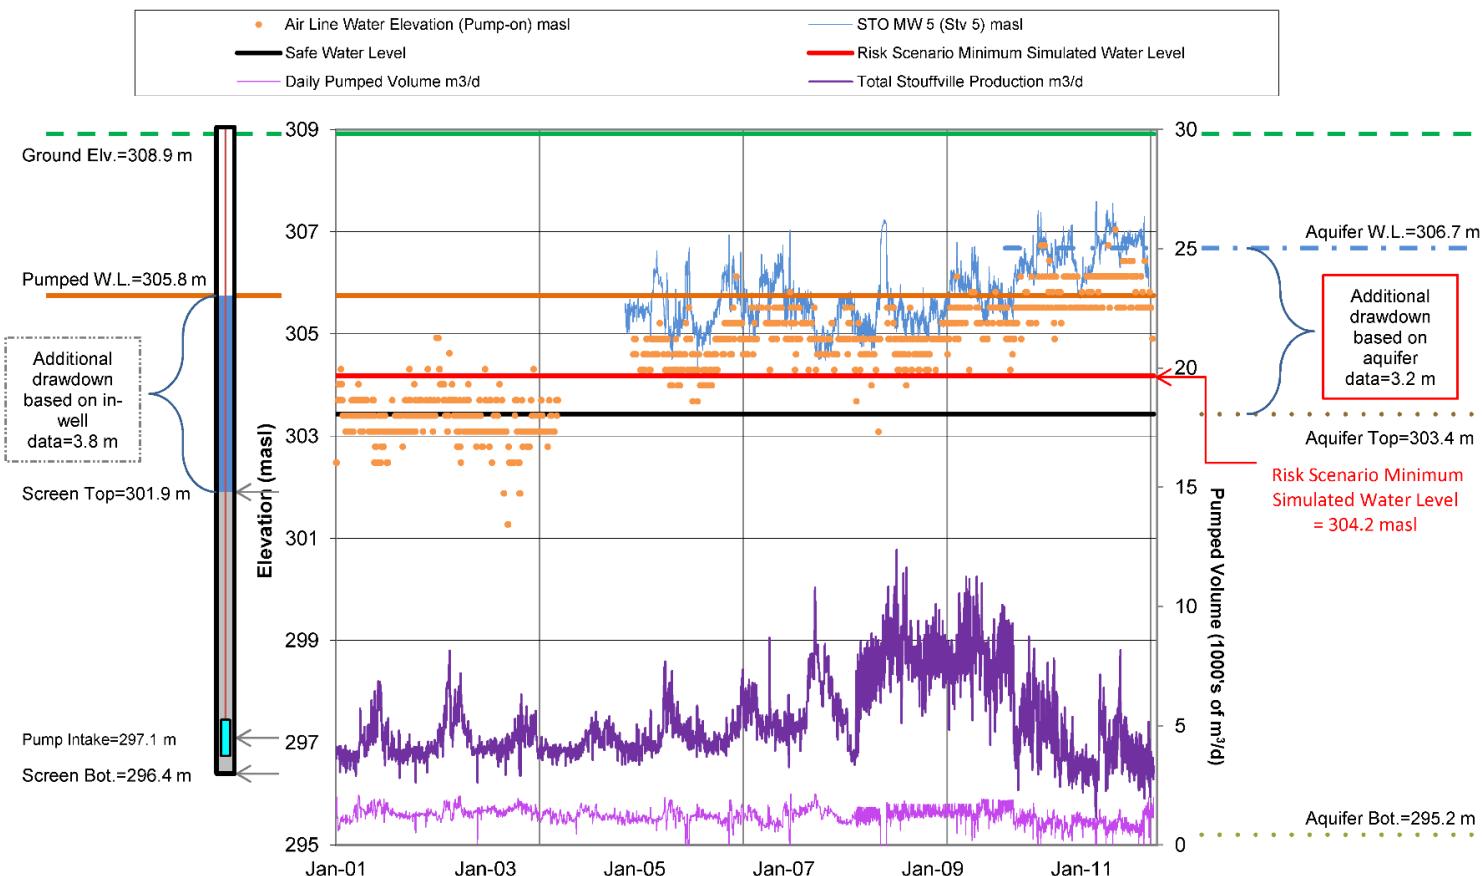

York Region Tier 3 Water Budget - Available Drawdown Hydrographs

Stouffville PW 3

York Region Tier 3 Water Budget - Available Drawdown Hydrographs

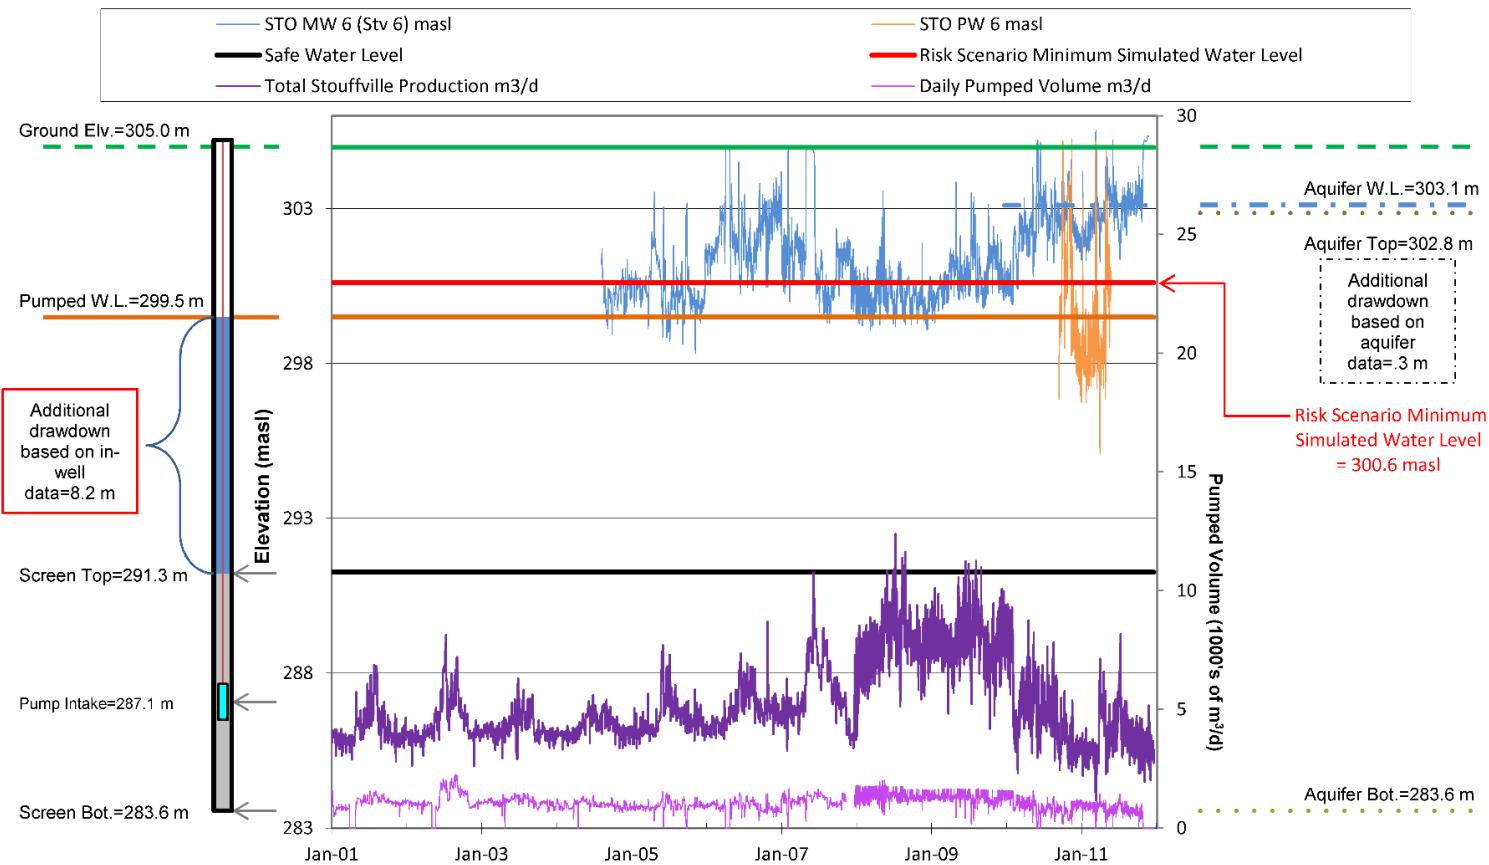

Stouffville PW 5

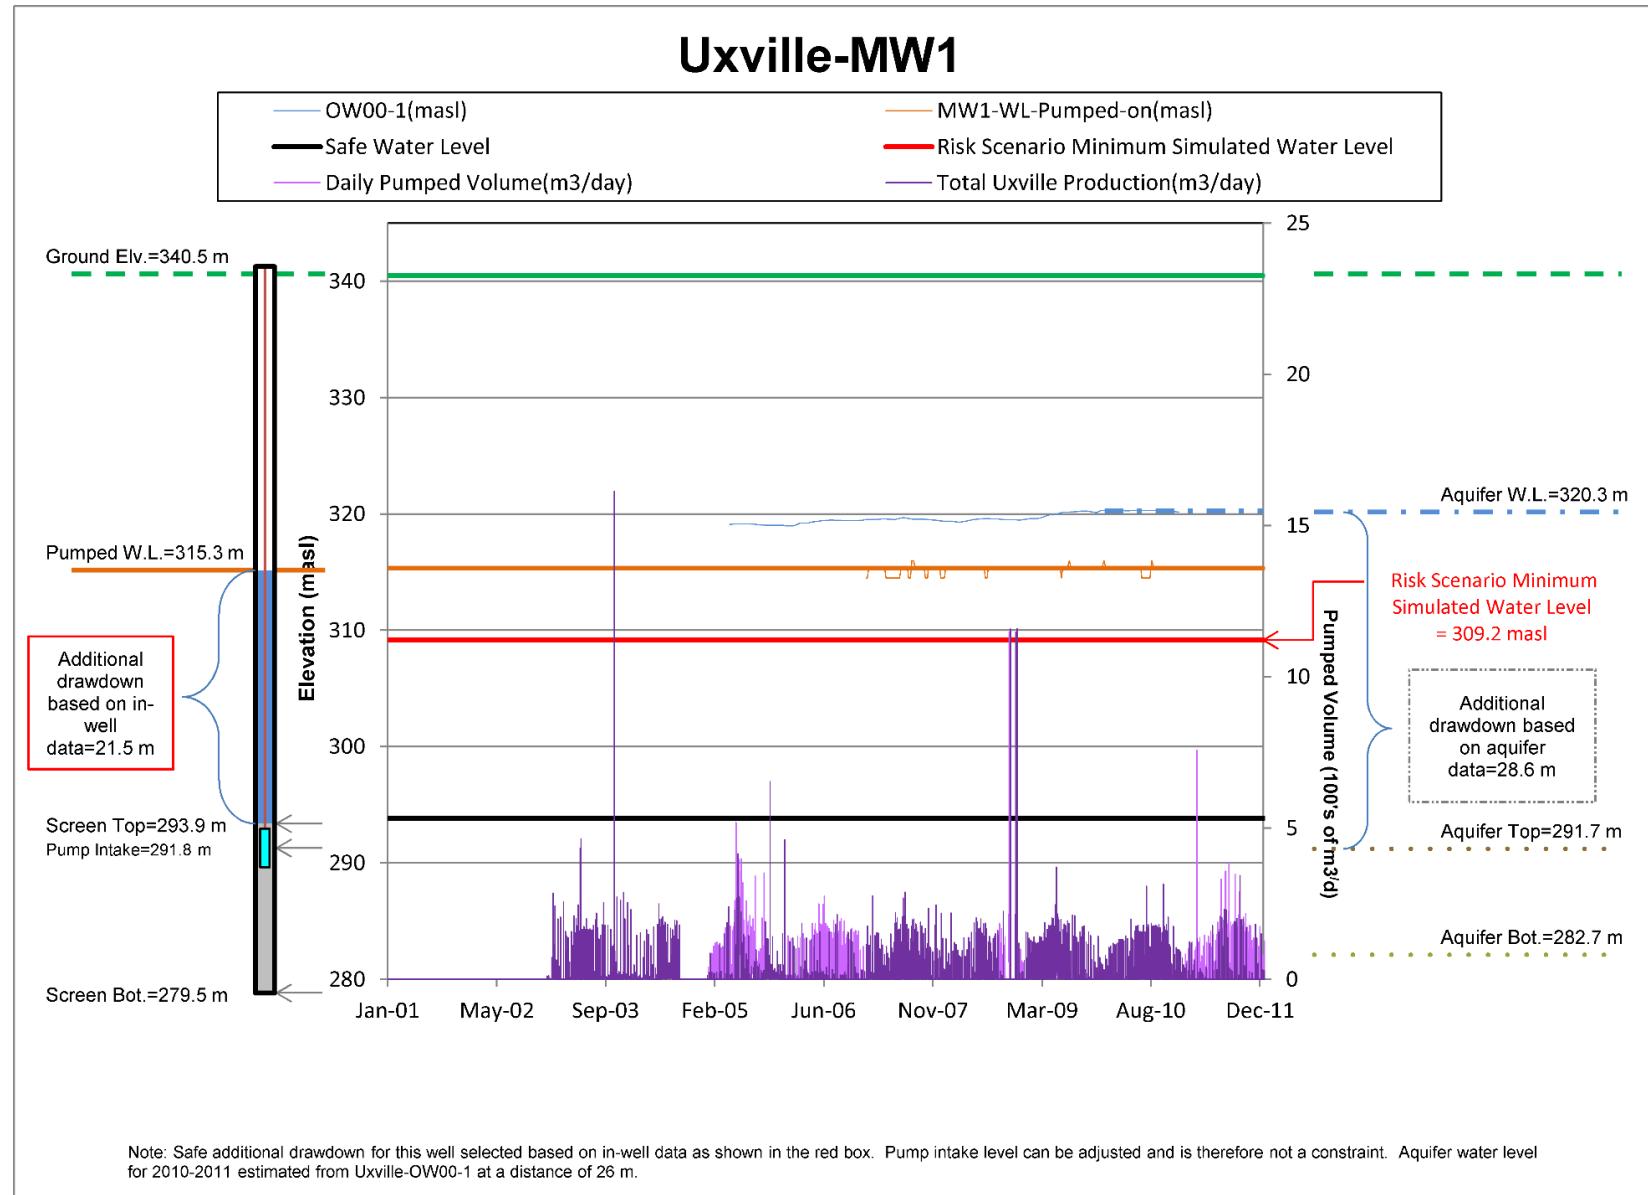

Note: Safe additional drawdown for this well selected based on aquifer data as shown in the red box. Pump intake level can be adjusted and is therefore not a constraint. Aquifer water level for 2010-2011 estimated from Stouffville MW#5 at a distance of 9 m.

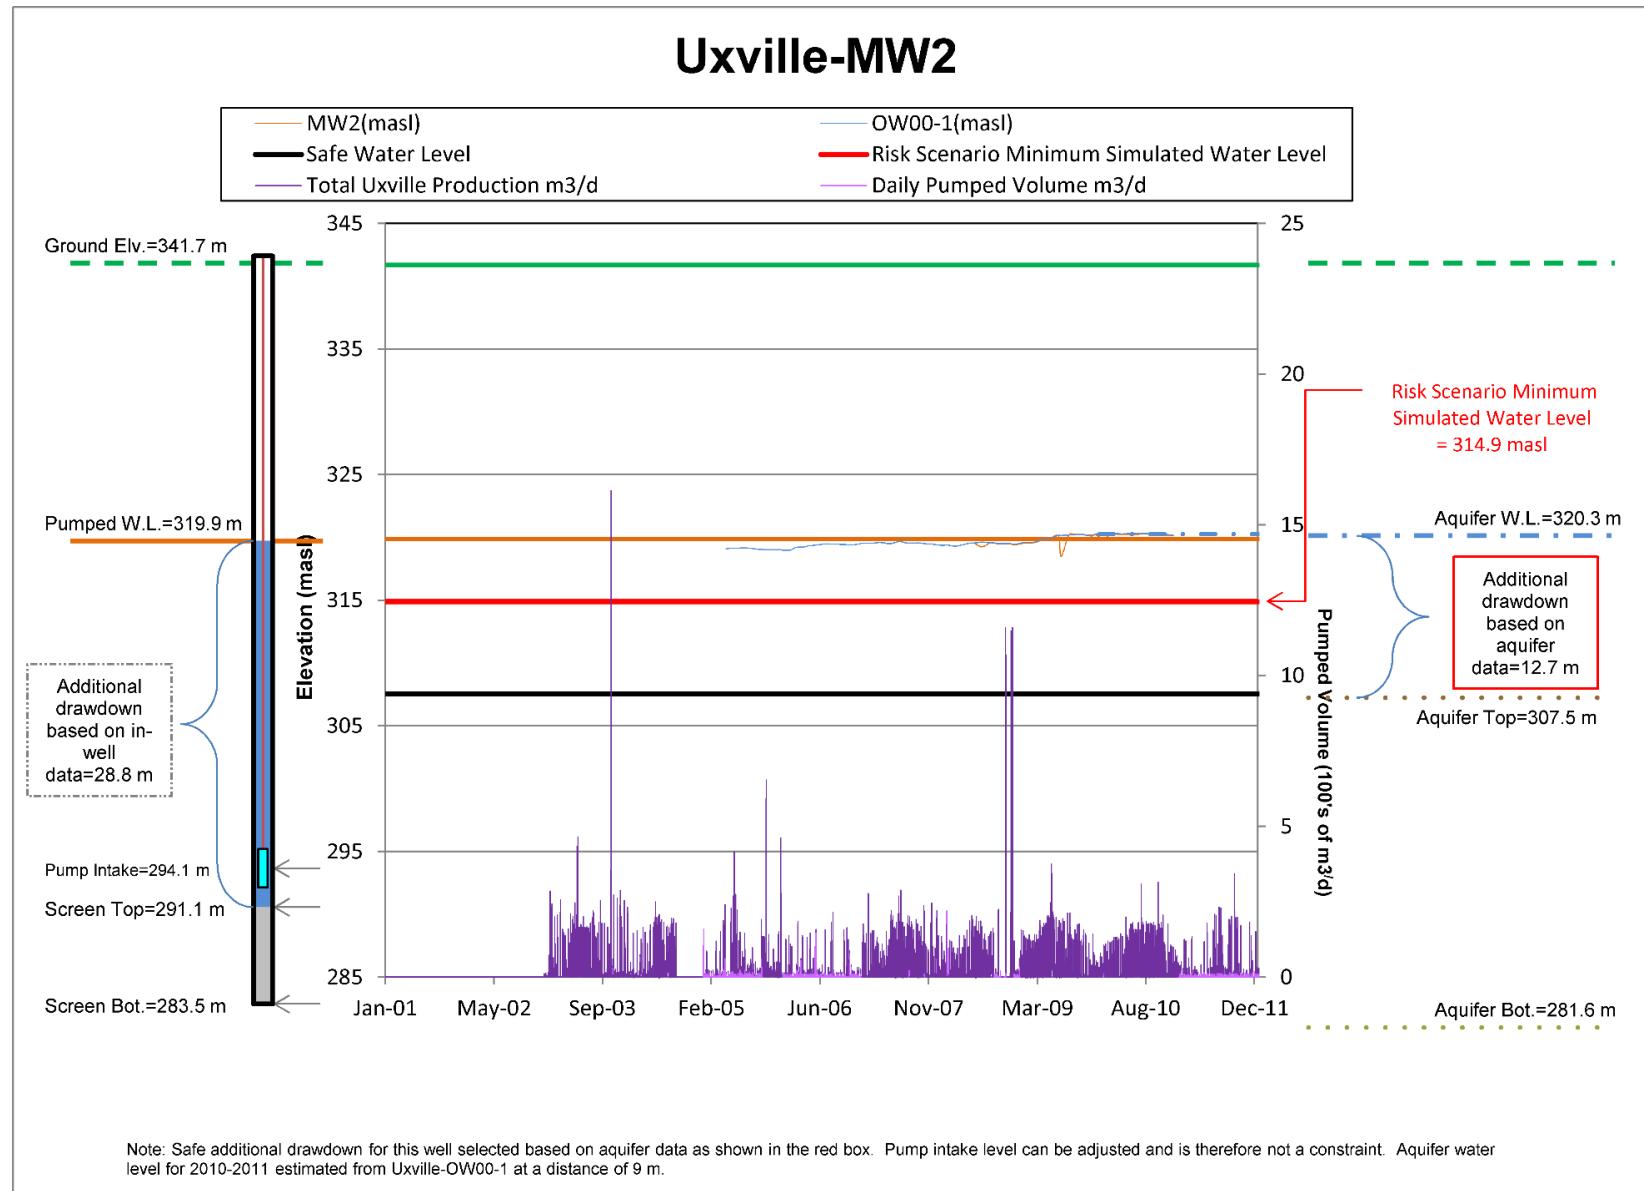

York Region Tier 3 Water Budget - Available Drawdown Hydrographs

Stouffville PW 6

Note: Safe additional drawdown for this well selected based on aquifer data as shown in the red box. Pump intake level can be adjusted and is therefore not a constraint. Aquifer water level for 2010-2011 estimated from Stouffville MW#6 at a distance of 6.4 m. An additional drawdown of 8.2 m has been selected based on in-well conditions due to the unconfined nature of the aquifer. (Dewatering of the unconfined aquifer is not considered an issue because it is unconfined (or, at worst, semi-confined by ORAC silts)).
